Overview

TMEngine

TMEngine is an open source [Translation Memory](#)™ manager written in Java.

TMEngine can be used either as an embedded library that manages translation memories in a Java application or as a standalone TM server via its REST API.

Java Library

REST API

REST Methods

The REST methods that TMEngine's server support are:

- [Create Memory](#)
- [List Memories](#)
- [Open Memory](#)
- [Close Memory](#)
- [Import TMX File](#)
- [Export TMX File](#)
- [Search Translations](#)
- [Concordance Search](#)
- [Rename Memory](#)
- [Delete Memory](#)
- [Stop Server](#)

Default TMEngine URL is `http://localhost:8000/TMEngine/`

Note

It is possible to select a custom port for the server, passing the `-port` parameter to the script used for launching it.

All methods return a JSON object with a `status` field. Applications must watch this field and verify that it is set to OK.

In case of error, the JSON response includes a field named `reason` that contains the error cause.

Create Memory

End Point: `[TMEngine URL]/create`

Send a `post` request to the method end point with these parameters in a JSON body:

Field	Required	Content
<code>id</code>	No	ID of the memory to create. The value of ID must be unique. Default value is current server time represented as the number of milliseconds since January 1, 1970, 00:00:00 GMT.
<code>name</code>	Yes	
<code>owner</code>	No	
<code>type</code>	No	Type of engine to use. Possible values are: <code>MapDbEngine</code> (default) and <code>SQLiteEngine</code>

Example:

```
{
  "name": "First Memory",
  "type": "MapDbEngine"
}
```

The server responds with a JSON object containing two fields.

On success, field `status` is set to `OK` and field `id` contains the ID assigned to the new memory.

Example:

```
{
  "status": "OK",
  "id": "1234567890987"
}
```

On error, field `status` is set to `failed` and field `reason` contains the error cause.

Example:

```
{
  "status": "failed",
  "reason": "Duplicated id"
}
```
